Heart failure: what a daily weight record can tell you

> *Small changes in breathing, swelling and weight can help your team act earlier.*

Understand the name

Heart failure does not mean the heart has stopped. It means it is not pumping blood as well as it should. Some people develop fluid retention, swelling or breathlessness. A treatment plan aims to improve symptoms and daily function.

Make readings comparable

If advised, weigh each morning after urinating and before breakfast, using the same scale, location and similar clothing. Record the date and weight alongside changes in breathing, swelling and usual activity. A rapid weight change is a clue, not proof of fluid in the lungs.

Ask for personal limits

A fixed 1.2-litre allowance is not appropriate for everybody. Ask about your daily fluid advice, what counts as fluid, and the weight-change threshold that should trigger a call. Your clinician may need to adjust the plan as your condition changes.

Do not improvise a medicine change

Follow an existing written clinician action plan. Otherwise contact your team before increasing a diuretic. Another patient’s prescription is not a safe substitute. Bring your record to appointments and discuss difficulties with daily tasks.

Know when to act

New or worsening swelling and breathlessness need prompt contact. Severe breathlessness at rest, chest pain, collapse or blue lips requires emergency help. Do not wait for a website reply.

> For a life-threatening emergency in India, call 112. Elsewhere use your local emergency number.

Questions you may have

Does weight gain always mean fat gain?

No. A rapid change may relate to fluid, but it needs assessment in context.

What to remember

Use weight and symptoms together with your personal action plan.
