Coughing with meals after stroke: check swallowing first

> Wanting someone to eat is natural. Safe swallowing needs to come before another mouthful.

Why meals can become difficult

After stroke, swallowing coordination may be affected. Difficulties can involve food, drinks and medicines. Coughing is not deliberate behaviour. Listen to what the person finds difficult and seek assessment.

Clues to report

Coughing, choking, food sticking, a wet-sounding voice, weight loss and repeated chest infections warrant attention. A clinician may refer you to a swallowing therapist and dietitian. Ask about mouth care too; tube feeding does not remove that need.

Soft does not automatically mean safe

The appropriate texture, drink thickness, positioning, pace and supervision depend on assessment. Do not try water to wash food down or start thickening drinks without advice. Tube feeding requires separate instructions.

Follow the written plan

Make sure each caregiver understands the allowed foods and drinks. Ask how medicines should be given. Stop offering more food when swallowing causes distress and obtain advice rather than trying another consistency at random.

When to seek help

Seek prompt assessment for swallowing difficulty or breathing symptoms after meals. Inability to breathe, speak or cough effectively, blue colour or collapse is an emergency. **Do not force water** or make a blind finger sweep; use appropriate choking first aid if trained.

> For a life-threatening emergency in India, call 112. Elsewhere use your local emergency number.

Questions you may have

Will a feeding tube always be needed?

Not necessarily. Assessment, nutrition needs and recovery guide the decision.

What to remember

The first question is not how much was eaten, but whether it was swallowed safely.
